# THE BRACHYURA COLLECTEI) BY THE U. S. FISH COMMISSION STEAMER ALBATROSS ON THE VOYAGE FROM NORFOLK, VIRGINIA, TO SAN FRANCISCO, UALIFORNIA, 1857-1888. 

By Mary J. Ríthbun, Second Assistanl Curclor, Division of Marinc Invertebrates.

The Albatross left Norfolk, Virginia, November 20, 1857, and arrived at San Francisco, California, May 15,1888 . The prineipal shore stations visited were as follows: Port Castries, St. Lucia; Bahia alnd the Abrolhos Islands, Brazil; Montevideo, Uruguay; seven places in Magellan Strait; five places on the west coast of Patagonia, or Magallanes territory, Chile; Lota and Tome, Chile; l'anama; eight of the Galapagos Iskands; Acrumbo, Mexico; Pichilingue Harbor, in La Paz Bay, Magdalena Bay, Mbrojos Point, and Cerros Island, Lower California; and San Clemente Island, California. During the voyage, 91 hanls of the trawl and dredge were marle and 31 casts of the tow net.

I'rol. Lesle A. Lee, of Bowdoin College, was assistant in eharge of the seientific staff during the experlition. It was his intention to report upon the Brachyma collected, but the pressure of other duties has delayed his studies on this group from year to year until in the antumn of 1897 he kindly transfermed the collection to the writer.

The braclyara number 151 species, of which 31 are new. Twentyform other species were undescribed at the time of the expedition, but have been made known from other ermises during the past ten years. With one exception the new forms are fiom the Pacific, and nearly all are from the coasts of lower Califormia.

The range of many West ludian shallow-water forms is extended southward to Capo St. Roque, Brazil; while from station 2762 , in the latitude of Rio de Janeiro, and at a depth of bit fathoms, we have the uncommon species, Tetraxanthns bidentatus (A. Milne-Ldwards), Mirropanope xanthiformis (A. Milne-Edwards), and Chasmocarcinus typicus Rathbun, known otherwise only from the West Indian region. At station 2763,671 fathoms, latitude $24^{\circ} 17^{\prime}$ sonth, oceur Grryon quinquedens Smith and Ethusimu ulysssicolu Smith, species inhabiting the deep waters off the eastern coast of the North American continent.

Another fact in the distribution of the Brachyura which needs to be emphasized is the increasing ummber of species common to western America and Japan. In a former paper I have alluded to the existence of Chorilia longipes Dana off the coast of Japau. Dr. Calman has recently recorded Philyra pisum De Haan from Puget Sound. In the U. S. National Mnsemm there is a large specimen of Chionocetcs opilio, supposed to be Japanese. Dr. Walter Faxou says that in the Museum of Comparative Zoology are examples from Japan of Tclmessus cheiragonus (Tilesins), which is distinct from T. acutidens Stimpson. To these may be added two Japanese species of Cancor (=Trichocarcinus), $C$. gibbosulus, and C. amphioctus, as noted below. The former stretches, on the American side, from Lower California to Alaska, while the latter has not yet been collected north of San Diego Bay.

The intimate relationship existing between the Caribbean and west American famas is accented by the discoveries made on this voyage. The snbspecies, Ethusa mascaronc americana, is found to be common to botl coasts. Among the new species described are many which have close relatives on the Atlantic side of the continent. They are arranged in the following list approximately according to the degree of resemblance between the allied species:

I'acific coust.
Osachila levis.
Hemus analogns.
Collodes tumidus.
Medtens lobipes.
Lissa aurivilliusi. >
Lissa tuberosia.
Actiea angrosta
Thyrolambrus crosus.
Palicus lucasii.

Calappa sanssurei.
Portunus (Achelous) angustus. Chasmocarcinus latipes.

## Atlantic coast.

Osachila tuberosa Stimpsou.
IIemus reistulipes A. Milne-Edwards.
Collodes inermis A. Milne-Edwards.
Merlens spinimanus (Milne-Edwards).
Lissa bicarinata Aurivillins.
Actara bifrons Rathbun.
Thyrolambrus astroides Rathbun.
(Palicus dentatus (A. Milne-Edwards).
$\{$ Palicus faxoni Rathbun.
Palicus alteruatus Rathbun.
Calappa angusta A. Milne-Edwards.
Portmus (Achelous) ordwayi (Stimpsou).
Chasmocarcinus typicus Rathbun.

In this report only the general localities and depths are given. Full details in regard to the dredging stations may be found in the Report of the U. S. Fish Commissioner for 158 [ [1891], pp. 422-424.

## MAIID ※.

## x. STENORYNCHUS DEBILIS (Smith).

Leptopodia debilis Smitir, Ann. Rept. Peatbody Acal. Sei. for 1870, 1871, p. 87.
Magdalena Bay, Lower California; off Cape St. Lucas; sonthern part of Gulf of California; Panama Bay; 7 to 31 fathoms (stations 2798, $2799,2823,2824,2825,2826,2828,2829,2831$. In a male from station 2798, Panama Bay, the rostrum is about $1 \frac{2}{3}$ times the length of the carapace; in specimens from all other stations the rostrum is short.

## 2．PODOCHELA HEMPHILLII（Lockington）．

Microrhynchus hemphillii Lockingron，Proc．Cal．Acad．Sci．，February 7，1876， 1877，VII，p．30．Bay of San Diego．
Inachoilles（Microrhynchus）hemphillii Lockington，Proc．Cal．Acad．Sci．，July 17， 1876，1877，VII，p． 75 （13）．
Podochela temuipes Ratirbun，Proc．U．S．Nat．Mus．，1893，XVI，p． 204.
Southern part of Gulf of California；off Cape St．Lucas and Magda－ lena Bay，Lower California， 10 to 31 fathoms（stations 2828，2829，2831）．

Mr．Samnel J．Holmes has examined the type of Nicrorhynchus hemp－ hillii Lockington and pronounces it the same as Podochela tenuipes．

## 3．COLLODES GRANOSUS Stimpson．

Collodes granosus Stimpson，Amn．Lyc．Nat．Ilist．N．Y．，1860，VII，p．194，pl．if， fig． 4.
Southern part of the Gulf of California， 10 fathoms，station 2828.
4．COLLODES ROSTRATUS A．Milne－Edwards．
Collocles rostratus A．Milne－Edwards，Crust．Rég．Mex．，1878，1．179；1879，11． ベメ゙ı，fig． 2.
Off the Rio de la Plata， $10 \frac{1}{2}$ fathoms，and off the（iulf of San Matias， Argentina， 52 fiathoms（stations 2766 and 2767）．

5．COLLODES TENUIROSTRIS Rathbun．
Collodes tenuivostris Ratilbun，l＇oc．Ǔ．S．Nat．Mirs．，1893，X̌VT，p． 230.
Magdalena Bay， 51 fathoms，and off Abreojos Point，Lower（＇alifor－ nia， 48 fathoms（stations 2833 and 2834）．

6．COLLODES TUMIDUS，new species．

## （Plate NLI，fig．1．）

Allied to C．inermis；carapace with forr elevated tubercles forming a cross near the middle．

This species is the Pacifie representative of C．inermis，from which it differs only slightly，and with the type of which it has been compared． The carapace bears near its middle four tubercles，of which two are on the median line，one gastric and one cardiac，and the other two are at the inner angles of the branchial regions．These tubercles are at the most elevated portions of the carapace，the gastric region being inter－ mediate in height between the cardiac and branchial．In the female， the cardiac tubercle is longer and appears like the base of a stout spine which has been broken off．In C．inermis the immer angle of the branchial region is depressed．In tumidus the granulation of the pos－ terior and lateral regions is less extensive than in inermis，there being almost no granules on the cardiae region．

The front，like that of inermis，is furnished with two blunt teeth near together．The postorbital tooth is subtriangular and slightly curved．

The basal joint of the antenna is wider than in inermis; the lobes of the onter margin are larger. The stermm of the male is gramulated; the abdomen of both sexes is nearly smooth; the first segment has a median tuberele.

Chelipeds smooth; lingers gaping widely to near the tips; dactylus with a short truncate tooth urar its base; pollex with a large tooth at one-third the distance from the proximal end. Amblatory legs stonter and shorter than in ( 6 incrmis.

Dimensioms.-Male: Length, 11.6 mm ; wilth, 9.5 mm. Vemale: Length, 10.3 mm .; width, 8 mm .

T'ype-No. 21571, U.S.N.M. One male from Magdalena Bay, Lower Califormia, 12 fathoms, station 2831.

Additional specimen.-A femate of this species was taken in the sonthern part of the (inlf of California, 10 fathoms, station $25: 3$.

## 7. BATRACHONOTUS NICHOLSI Rathbun.

Off the west coast of Lower California, from Cape St. Incas to Abreojos Point, 12 to 51 fathoms, stations $2529,2831,2833$, and 2831 .
This speries was founded on two small dried females. The present specimens are larger, show both sexes, and indicate that the species is very closely related to P. frayosu.s Stimpson of the West Indies. It differs chiefly in the longer postorbital tooth, which is as long as the eye; in the more elevated preorbital borler, wheh at its highest point forms a tooth, or in some specimens a spine; in the coarser gramlation of that part of the stermm of the male between the chelipeds; and in the evenly toothed tingers of the male, while in frugosus the pollex has a larger tooth at its middle. The female is narrower than the male. The tuberculated portions of the different regions are more extensive than in the types.

Dimensions.-Male: Length, 9 mm .; width, 7.9 mm . Vemale: Length, (3.5) mmin wilth, ri. 4 mm .

## 8. DASYGYIUS DEPRESSUS (Bell).

Sonthern part of the (inlf of Califormia, 21 and $26 . \frac{1}{2}$ falhoms, stations

## 9. DASYGYIUS TUBERCULATUS (Lockington).

Iunches luberculatus lonckingron, Proc. ('idl. Aciad. Sci., Febrnary 7, 1876, 1877, VII, !. 30.
Mierorhyuchu* (Iunchus) tuberculatus LockingTon, Proe, Cal. Acarl. Sci., July 17, 1876, 1877, V11, 1. 64.
Neorhyuchus mexictums Rathbun, I'oo. U. S. Nat. Mus., 1893, XVI, p. 233.
l'anama bay, 7 and 16 fathoms, stations "S00 and 2802.
The inentity of my species ame that of Lackington has been determined by Mr. S. J. Holmes, who has oxamined the types of both.

## ro. INACHOIDES MAGDALENENSIS Rathbun.

Southern part of Gulf of Califormia, and off west coast of Lower Californa, from Cape St. Lacas to Abreojos Point, $\tilde{y}_{2} \frac{1}{2}$ to fathoms, stations $2823, \because 8 \div 4,2430,2831,2832$, and 2835 .

## ir. EURYPODIUS LATREILLII Guérin.

 pl. xiv.

From off Gulf San Matias, Argentina, to Magellan Strait, 10 to 61 fathoms, stations $2768,2770,2771,2773$ to 2759; also at (iregory Bay and Sandy Point, in Magellan Strat, and Mayne Marbor and Latitude Cove in Magallanes 'Territory, Chile.

## 12. ANAMATHIA CORNUTA, new species.

(Ilato NLI, lig. 2.)
Rostrum longer then the postfronlal portion of the carapace; lateral margin with two lou!g spines; dorsal surface with nine short spines.

Surface closely covered with tuberculiform cutaneons vesicles, among which are a few curved hairs. Thbercles and spines of the carapace as follows: Gastric region with thee short, one median, the lateral in advance of the median; cardiac and intestinal regions oach with one, short and conical ; branchial region with two short, the posterior smaller and nearer the median line; hepatic and branchial regions each with a long, slemder marginal spine directed ontward, upward, and forward. Rostral horns very long and slender, nearly equaling or exceeding onelald the ratire lensth of the carapare, and extending nearly to the base of the rostrum; they are slemler, widely divergent, slightly arehed. Preorbital spine short, slender, not reaching the base of the rostral horms; postorbital tooth rombled. Basal joint of antema with a short tooth or spine at the anterolateral angle. Pterygostomian ridge with three or fom tubercles. A blint rounded tooth at the angle of the burcal cavity.

Cheliperls slender. Merus triangulate; outer face with a low blant ridge; upper margin with a sharp terminal spine, and a broad subacute tooth near the proximal end. Carpus with a superior longitndinal nueven crest, and a tuberele on the onter smrface near the distal end. Propodas compressed, with a thin upper edge; dactylus more than onehalf the superior length of the proporlus. Fingers with a narow gapo along their hasal third; pehensile edges crenate. Meral joints of ambulatory legs with a short spine, which decreases in sizo and acuteness from the first to the fourth pair, where it is a blant lobiform prominence.

Dimensions of Inamathin cornuta.

| Sex. | Length from tip of horis to middle of josterior utargin. | Length from base: of horns. | Length of horns. | Width exclnsive of spines. | Length of brauc:hial spine. |
| :---: | :---: | :---: | :---: | :---: | :---: |
| Malo.............. | mim. <br> 35.9 <br> 50.2 | mm. $\begin{aligned} & 19 \\ & 25 \end{aligned}$ | min. <br> 17.8 <br> $2(3.5$ | mm. <br> 14.5 <br> $\because 0.2$ | mm. $\begin{aligned} & 6.2 \\ & 9.0 \end{aligned}$ |

Types.-No. 21572 , U.S.N.M.; five males and two females, from northeast of Indefatigable Island, Galapagos Islands, 392 fathoms, station 2818.

## 13. CHORILIA LONGIPES Dana.

Chorilia longipes Dana, Amer. Jonr. Sci., 1851, 2d ser., XI, p. 269; Crust. U. S. Expl. Expea., 1852, I, p. 91 ; 1855, pl. 1, fig. 5.
hymestenus longipes Miers, Ratibun.
North of San Clemente Island, California, 414 fathoms, station "839.
14. LEUCIPPA PENTAGONA Milne-Edwards.

Leucippa pentagona Milxe-Edwards, Anin. Soc. Entom. France, 1833, II, p. 517, pl. xyir, B, figs. 1, 2 (pantagona). Chile.
Lencipra msenade Mhene-Fiwahbs and Lucas, Doorbigny's Voy. l'Amér. Mérid., 18:13, VI, 1't. 1, 1. 9 ; 1817, 1N, pl. v, lig. 3. Patagonia.
1.cucippa luvis Dana, Amer. Jour. Sci., 1851, 2d ser., XI, p. 273; Crust. U.S. Expl. Exped., 1852, I, p. 135 ; 1855, pl. vi, fig. 5. Rio de Janciro.
I believe that $L$. pentagona, ensenarla, and lavis are one and the same species, as a large series of specimens in the collection from off the Rio de la Plata ( $10 \frac{1}{2}$ to $11 \frac{1}{2}$ fathoms, stations $2764-2766$ ) and from off the Gulf of San Matias, Argentina ( 52 fathoms, station 2767 ), show a great amonnt of variation in the breadth of the carapace, prominence of the lateral teeth, and in the acnteness and divergence of the rostral horns. The average individuals are similar to that figured as $L$. ensenade by Milne-Edwards and Lucas. A single small specimen is labeled "Station 2833," which is in Magdalena Bay, Lower California, 51 fathoms.
15. EPIALTUS DENTATUS Milne-Edwards.

Epialtus dentatus Milne-LDwaris, Iíist. Nat. Crnst., 1834, I, 1. 345.
Port Otway, Magallanes Territory, Chile.
16. EPIALTUS NUTTALLII Randall.

Epialtus nuttallii Ranisall, Jour. Acad. Nat. Sci, l’hila., 1839, VIII, 1, 109, 11.111 (Libinia nuttallii).
Ballenas Bay, Lower California.

## 17. TYCHE LAMELLIFRONS Bell.

Tyche lamellifrons Bell, Proc. Zool. Soc. London, 1835, III, p. 173; Trans. Zool. Soc. London, 1836, II, p. 58, pl, Xil, lig .3.
Southern part of the Gulf of California, 7 fathoms, station 2825.

## 18. TYCHE EMARGINATA White.

Tyche emarginata Wirte, Ann. Mag. Nat. 11ist, 1817, XX, p. 206.
Off Uape St. Roque, Brazil, 20 fathoms, station ${ }^{6} 758$.
19. LEUROCYCLUS TUBERCULOSUS (Milne-Edwards and Lucas).

Salacia tuberculosa Mileme-Enwanins and Litcas, D’Orbigny's Voy. l'Amér. Mérirl., 1813, VI, Pt. 1, p. 13 ; 1847, IN, pl. 11.
Off the Rio de la Plata, 10. to $11 \frac{1}{2}$ fathoms, stations 2764, 2765, 2766.
20. CHIONCECETES TANNERI Rathbun.

Chionocetes tanucti Ratimun, Proc. IT. S. Nat. Mas., 1893, XVI, p. 76, pl. iv, figs. 1-4.

North of San Clemeute Island, California, 114 fithoms, station 2839.

## 21. HEMUS ANALOGUS, new species.

Outer margin of first mocable joint of antenna strongly arcuate.
This species is so closely allied to Memus cristulipes A. Milne Edrards of the Caribbean region that the differences are only comparative. The carapace is higher at the cardiac region and slopes more abruptly down toward the fiont. The hollow in cristulipes on the posterior part of the branchial region on either side of the cardiac region is replaced in analogus by a slightly convex surface. 'The side margins of the rostrum are convex; in cristnlipes straight. The rostral tecth are nearer together in analogus and terminate in a sharp spinule; in cristulipes they terminate in a stout tubercle. The preorbital angle is rounded, with sides rectagular; in eristulipes the anterior margin of this angle is oblique. The outer margin of the first movable joint of the antenna is curved, while in cristulipes it is straight, or nearly so, being parallel to the sides of the rostrum. The meral joints of the ambulatory legs are narrower and their marginal dentieles stronger than in the $A$ tlantic species.

Dimensions.-Female: Length, 8.2 mm ; width, 6.3 mm .
Type.-No. 21573, U.S.N.M. An adult female from the southern part of the Gulf of California, 10 fathoms, station 2828.

Addituonal specimen.-One immature female was taken at the same locality.
22. PELIA ROTUNDA A. Milne-Edwards.

Pelia rotunda A. Milne-Finwains, Crust. Reg. Mex., 1875, p. 74, pl. xvi, fig. 4.
Off Cape St. Roque, Brazil, 20 fathoms, and off the Rio de la Plata, $10 \frac{1}{2}$ to $11 \frac{1}{2}$ fiuthoms, stations $\because 755, \mathscr{2} 64,2765, \because 766$.
23. PELIA PACIFICA A. Milne-Edwards.

P'elia pacifica A. Minne-Enwarins, Crust. lég. Mex., 1875, p. 73, pl. xvi, fig. 3.
Magralena Bay, Lower California, 1’’ fiathoms, station '2S:31.
24. LIBINIA SETOSA Lockington.

Libinia setosa Lockintiton, Proe. Lal Acad. Nei., July 17, 1876, 1877, VII, p. 68.
Magdalenal Bay, 12 to 51 fathoms, and olf Abreojos Point, Lower California, $5 \frac{1}{2}$ fathoms, stations $2831,2832,2833$, and 2835.

All the specimens are young. The four branchial spines forming a rhomboid are rather long, as are also three of the median spines, namely, the posterior of the gastric spines, the anterior cardiac and intestinal. The posterior gastric spine of alalts is wanting in the yomug and the tulberele on either side of the anterior cardiac spine is much reduced.
25. LIBINIA SPINOSA Guérin.

Libimin spimosa Gublin, leom. J. Auim., Crust., jl. ix, lig. 3-Mune-Edwarms, Hist. Nat. Crust., 18:31, 1, p. 301.
Off the Rio de la Platal, 10. fathoms, station 2766.
26. LIBINIA COCCINEA (Dana).

Libinia cocrine" MaElis, Challonger liept., Zool., 1886, XVII, 1. 73.
Off Gulf ol San Matias, Argentina, $5 \mathfrak{D}$ lathoms, station 2767.

## 27. LIBINIA SMITHII Miers.

Libinial hami A. Munv-EmWabls, Miss. Sci, Cap Horn, I891, VI, Crust, pī, pl 1, figs. 1-6.
Magellan Strait, 36: fathoms, and off Magallanes Territory, Chile, (il to 1,050 fathoms, stations $2750,2783,2751,2787$, and 2788 .
28. LISSA TUBEROSA, new species.
(Plato XLI, fig. 3.)
Branchial region with two large protuberances; postlateral margin sinuons; two crests on the curpal joints of the ambulatory legs.

Carapace with two merlian tuberculated prominences, the gastrie higher than the carliace, the latter continned backward along the median line to the posterior margin. A ridge rumning oblíjuely backwari from the gastric prominence is almost entively ocrupied by two protuberances, one at its midale amd one at the postero lateral angle of the carapace, which presents aromoded or oblignely trumeate outline. The simus of the postero lateral margin is more shallow than in L. biearinata Amivillins. Margin of hepatic region with a taherele; of branchial region with several tubereles and a blont tooth at its middle. Hepatic region nearly vertical. Front with a shallow median emargination, from which the margin slopes obliquely backward or is almost transverse; onter corners with a slight tootli, most producerl in yomgs specimens. Preorbital tooth subacute or obtuse.

Chelipeds leavy in the male. Ischimm with a tooth on its inner margin; merus with a tridentate crest on the superior margin. Carpus with surface uneven, a tuberele at the inner angle. Hands broan, compressed, widening distally, inner surface tuberenlate; lower margin of propodus with a sinus near its middle. Dactylus with an acnte upper margin. Fingers gaping for their basal half. Cheliperls of female much smaller than of male.

Ambulatory legs eristate as in bicarinuta. 'The crest on the meral joints has a thin triangular tooth at the distal end; carpal joints with two triangular erests side by side, divergent from each other, and forming a cup on the upper surface. Propodal joints with a single triangular superior crest, a tuberele on the anterior and josterior surfaces, and with swellinges at the articulation with the dactylns.

The surface of this eral) is covered with a dense, short, vascular pubescence.

Dimeusions.-Male, station 28.8: length, 13.6 mm.; willth, 13 mm . Male, station 289.1: Length, 16.9 mm.; winth, 15.8 mm . Female, station 2825: length, 14.1 mm ; wilth, 14.5 mm . Female, station 2828: Length, 12.3 mm . ; width, 11.5 mm .

This species is distinguished from $I$. bicarinata by the wider rostrum, with a median emargination instead of a deep eat, by the shallower postlateral simuses, hy the large protuberance at the midale of the branchal ridge, and by the double crest on the earpal joints of the ambulatory legs.

Typers.-No. 21574, U.S.N.M. Two males, station 2824, 8 fathoms.
Distribution.-'This species was taken at four stations in the southern part of the (inlf of California in 7 to 10 fathoms, stations 28:4, 2825, 2826 , and 2828 .

At two stations outside the (inlf of California were taken two specimens of hisst, which appear specitically distinct from the above and we more closely allied to I. bicariunta. These I have named-
29. LISSA AURIVILLIUSI, new species.
(1'lato NLI, lig. 4.)
Branchial vidye narrow; postlateral margin concace; carpal joints of first three pairs of ambulatory legs with one erest.

In this species the male amd female are wider than long. The gastric prominence is small and angular the obligne ridges leading from it are sharp and finely tubereulate, with only a shallow tooth at the middle in place of the romm knob in luberosa, and terminate in a raised tooth at the postlateral angle. The rardiac hamp is small, and the median ridge extending back fom it is narow. Lateral margins tubereulate, with a shallow tooth at the midrle and one farther back. Postlateral margin not simuons as in the other two American sjecies, but presenting a single shatlow sims extending the ontire length of the margin. Median noteh of the front shallow ; onter teeth prominent. The cheli-
peds present no distinctive characters. The ambulatory legs are most like those of bicarinata in having only one crest, the posterior, on the earpus of the first three pairs of ambulatory legs, the anterior crest of tuberosa being represeuted by a tooth.

Dimensions.-Male: Length, 12.5 mm .; width, 13 mm . Immature female: Length, 9.8 mm. ; width, 10 mm .

Type.-No. 21575, U.S.N.M. One male from off Cape St. Lucas, 31 fathoms, station 2829.

Additional specimen.-An immature female was taken in Magdalena Bay, 12 fathoms, station 2831.
This species resembles $L$. bicarinata, and differs from L. tuberosa in its narrow ridges and in the single crest of the carpus of the ambulatory legs. It differs from both in its greater width and in the outline of the postero-lateral margin.

## 30. LEPTOPISA SETIROSTRIS Stimpson.

Tïarinia setirostris Stimpson, Bull. Mus. Comp. Zool., 1871, II, p. 114.
Leptopisa setirostris Stimpson, Bull. Mus. Comp Zool. 1871, ll p. 114, in text.
Macrocoloma tenuirostra Ratibin, Proc. U. s Nat. Mns, 1892, גV, p. 252, pl. xxxili, fig. 1.
Off Cape St. Roque, Brazil, 30 fathoms, station 2758.
31. MACROCELOMA TRISPINOSUM (Latreille).

Pisa trispinosa Latreille, Encyc. Méth., Hist. Nat., Entom., 1825, X, p. 142. Macrockloma trispinosu Mielzs, Jour. Linn. Soc. London, 1879, XIV, p. 665.

Microphrys bicornutus A. Milne-Edwards, Nouv. Archiv. Mus. IIist. Nat. Paris, 1872, VIII, p. 247.
Abrolhos Islands, Brazil.
38. MICROPHRXS BRANCHIALIS, new species.
(Plate XLI, fig. 5.)
Microphrys, species, Ratilbun, Proc. U. S, Nat. Mus., 1892, XVV, 1. 254.
Postcro-lateral angle with one spine; antero-lateral margin unarmed; anterior branehial region swollen.

Carapace triangular. Anterior portion of the branchial region covered by an oblique oblong protuberance, highest in its posterior portion, sloping gradually downward anteriorly and covered with tubercles. Gastric region with three tubercles on the median line, a cluster of three on each side anteriorly, and a transverse row at the posterior end. One tubercle on the genital region; ten on the cardiac, of which two are median. Posterior branchial region with several tubercles, the chief of which are arranged in two longitudinal rows; postero-lateral angle with a spine curving upward. A row of blunt tubercles above the posterior margin. -Margin of the hepatic region with only a small tubercle; vertical side of the branchial region with scattered tubercles, and two lines of tubercles continued to the pterygostomian region. Anterior and lateral regions hairy. Rostrum deflexed, with two flattened, triangular, acute horns, pointing directly forward, and separated by a $V$-shaped sinns reaching one-half the length of the rostrum. Preorbital tooth blunt, denticulate. Two superior orbital fissures on either side of a ronnded lobe; postorbital tooth blunt. The basal antennal joint bears at its antero-lateral angle a long, broad, blunt spine or

[^0]Proc. N. M. vol. xxi- 37
tooth, emrved inwad and mpward and with eremated onter margin; a short, blunt tooth at the base of the second joint; a tooth on the outer margin, forming part of the wall of the orbit, and two laminate teeth between the onter sinns and the buccal cavity.

Chelipeds one and one-third times the lengh of the carapace in the male. Upper surface of the merns and carpus with some seatered tubereles; outer surface of merns with a longitudinal row ; also two or three tubereles at the proximal end of the onter lower margin. Palm long and narrow, margins parallel, superior length twice the width and mome than one and a half times the length of the dactylus. Pollox not bowed downward as in $1 /$. platysoma Stimpson. The chelipeds of the fomale differ in being more slender and abont nine-tenths the length of thocarapace. First pair of ambulatory legs reaching hatf the length of the palm of the chelipeds in the male and equaling the chelperls in the female. Meral joints of ambulatory legs armed with spines and tubereses on the superior and outer or posterion surfaces; carpal joints with two or three spines; margins hary.

IHimensions.-Malo: Length, 15.3 mm . ; width, ineluding spines, 14 mm . exeluding spines, $11 . \mathrm{s}_{\mathrm{mm}}$. Female: Length, 15 mm . width, including spines, 1.4 mm ; exchding spines, 11.5 mm .
 1Bay, Lower California, 12 lathoms, station $2 \times 31$.

Adlitimal localitics-Off Abreojos Point, Lower California, 48 fathoms, station 2831: Gulf of California, northwest of Guaymas, 22 fathoms, station 3012.

## 39. MICROPHRYS TRIANGULATUS (Lockington).

Charles Island, Hood Island, and Duncan Island, all of the (ialapagos group.

## PARTHENOPIUAE, <br> 48. THYROLAMBRUS EROSUS, new species.

(I'lato XLII, fig. 1.)
Surface tuberculate and eroted; posterior margin transierse and bordered by blunt teeth or lobes; hand dentate or lobate, not spinate.

This species, although possessing a strong resemblance to $T$. astroides, differs noticeably in the shape of the carapace and the character of the surface. The carapace is longer, the outline more pentagonal; the lateral and posterior margins, instead of being thin and

[^1]acntely dentate as in astroides, are thick, and the posterior margin is bordered by small but prominent lobes. This margin is almost transverse, the posterior border of the branchial expansion not being inclined forward as in astroides. The lateral margin of the branchial region is much longer than in astroides, and the hepatic region is much more prominent. The general elevations and depressions of the carapace are similar to those of ustroides. The surface is covered with small irregular pits, separated by low, smootl, retienlating ridges. The higher portions of the carapace bear at intervals tubercles covered with depressed granules. Under the lens the entire surface is seen to be deusely and finely punctate.

The merus of the chelipeds is less thick than in astroides, and is armed with blunt tubereles or spines, as follows: A large tubercle on the distal third of the posterior margin; three or four rather slender blunt spines on the proximal half of the same margin; three prominent tubercles on the proximal half of the anterior margin; three low tubercles on the inferior margin; one tubercle on the superior surface. The hands are broader than in "stroides, and broader at the base of the fingers than elsewhere, the upper margin of the outer surface being concave. The fingers are thick, especially the pollex. The armature is less striking than in astroides; instead of the elongated spines in that species, there are triangular, acute, and spinulous teeth. Of these there are five or six on the lower margin of the propodus, three being on the pollex; they are direeted obliquely inward. The upper surface is deeply concave, and is bordered inwardly by three teeth, the median large and rounded. Dactylus with three small spines on the superior border of the inner surface. The surface of the chelipeds is similar to that of the carapace, except that the hands are rougher and more spinulous. The meral joints of the ambulatory legs are bordered by spinulous lobes or teeth; the propodi and dactyli are covered with spiuules: surface of meri and carpi relatively smooth.

Jimensions of three specimens of Thyrolambrus crosus from station 28.9.

| sex. | Length. | Posterior widtll. | Width at anterior angles of branchial region. |
| :---: | :---: | :---: | :---: |

Trichocarcinus gihbosulus Mens, Proc. Zool. Soc. London, 1879, p. 34.
Magdalena Bay, Lower California, 51 fathoms, station 2833.
There are specimens in the U. S. National Masemm from Granite Cove, Port Althorp, Alaska (W. H. Dall); off Cape Orford, Oregon, 35 fathoms (station 3094); San Francisco, California (D. S. Jortan); Monterey (Dr. O. A. Canfield); Monterey Bay, 13 and 19 fathoms (stations 3138 and 3142 ); Catalina Harbor, 30 to 40 fathoms (W. H. Dall); San Diego, 10 fathoms (H. Hemphill); San Diego Bay, 6.2 fathoms (station 3621); San Geronimo Island, Lower California, 7 fathoms (A. W. Anthony); and from Japan (II. Loomis).

## 55. CANCER AMPHICETUS, new name.

Trichocarcinus dentatus Miers, l'roc. Zool. Soc. London, 1879, p. 34.
Magdalena Bay, Lower California, 12 fathoms, station 2831; off Cerros Island, 44 fathoms, station 2S38. Three specimens, too young to be illentified with certainty, were taken off Abreojos Point, in 5! fathoms, station 2835 .

In subsequent cruises of the Albatross, this species has been taken at four stations in the Gulf of California, 12 to 36 fathoms (stations $3012,3015,3032,3033$ ); in San Diego Bay, California, $4 \underline{2}$ fathoms (station 3591); in Hakodate Bay, Japan, $11 \frac{1}{2}$ and $15 \frac{1}{2}$ fathoms (stations 3656 and 3659) ; and in the Gulf of Tokio, 169 fathoms (station 3661). The species was also collected at Fusan, Korea, by Mr. P. L. Jony.

## 56. ACT ÆA ANGUSTA, new species.

(Plate XLII, fig. 2.)
Carapace narrow, mosteriorly lobulaterl; lateral lobes dentiform; fingers rou!f/.

Carapace narrow, slightly convex, lobnlate on the posterior as well as the anterior half; lobules gramulous. The posterior half of the mesogastric region is long, and its sides are distinctly convergent backward; the depressions which form its lateral borders are contimed posteriorly in divergent lines, thins forming a figure the shape of an hour-glass. On either side of this there is a large branchial lobnle, not distinctly limited posteriorly. Front slightly deflexed, its margin visible in a dorsal view; lobes oblique, nearly straight, separated by a broad V-shaped motch. Lateral lobes four, besides the orbital, dentiform, the first very short, the second twice as long, the third much the longest. Inner suborbital lobe rounded, prominent.

Chelipeds covered with spiniform tubercles, the carpus deeply grooved, the tubercles on the hands arranged in longitudinal rows. Fingers deeply grooverl, the intervening ridges ronglı with spiniform tubercles. Ambulatory legs gramulate.

Dimensions.-Female: Length, 4.5 mm . ; width, 6 mm .
Type.-No. 21578 U.S.N.M. One immature female, off Hood Island, Galapagos Islauds, 20 fathoms, station 2812.

This species resembles $A$. setigera (Milne-Edwards) and A. dorii Stimpson in the ornamentation of the carapace and in the chelipeds; it differs from them in being narrower and posteriorly areolated, and having dentiform lateral lobes. It resembles A. bifroms Rathbun in its proportions and lateral lobes, and differs in its front, posterior areolations, and ronglened and grooved fingers.

## 57. ACTÆA INORNATA, new species.

> (Plato XLII, fig. 3.)

Carapace narrow, granulate, mubescent, not lobulate.
Carapace rather narrow for the genus; very convex antero-posteriorly, slightly so trunsverely; entire surface of crab covered with a short, dense pubescence, which must be removed to sce the character of the surfice beneath. The regions of the carapace are faintly outlined, and are not lobulated as in typical $A$ etcen, although there are traces of shallow furrows on the branchial region. The surface is sparsely ornamented with fine grannles, most numerous along the lateral margins. These margins are cut by three shallow notehes into four lobes. A median furow extends from the gastric region down to the front, which is divided by a slight emargination into two slightly simous and oblique lobes. The basal joint of the antenna does not reach as far forward as the inner angle of the orbit.

The chelipeds are nearly equal. The carpus and manus are covered with depressed granules larger than those of the carapace. The fingers are furrowed, gramulate, and white; their prehensile teeth are irregnlar. The dactylus is longer than the superior margin of the propodus; the pollex is not deflexed. The single specimen taken is a female, apparently adult.

Dimensions.-Female: Length, 4.3 mm ; width, 5.6 mm .
Type.-No. 21579, U.S.N.M. One female, from off Cape St. Roque, Brazil, 20 fathoms, station 2758.
58. OZIUS VERREAUXII Saussure.
()zins terreauxii Saussure, liev. May. Zool., 1853, 2l sor., V, p. 359, pl. Xir, fig. 1.

James Island, Chatham Island, and Indefatigable lsland, of the Galapagos.
59. OZIUS AGASSIZII A. Milne-Edwards.

Ozius agussizii A.-Milne-EDwards, Crust. Rég. Mex., 1880, p. 279, pl. Ly, fig. 1.
Duncan Island, Galapagos.
60. MEDAUS LOBIPES, new species.
(Plate XLIV, fig. 1.)
Ambulatory legs with lobate crests.
Carapace shorter and broader than in M. spinimanus Milne-Edwards; lobules similar in shape and position to those of that species. In the largest specimen the tuberculation of the lobules is less extensive than in smaller specimens, and also less extensive than in the somewhat larger individual of M. spinimumus, with which it is compared. Posterior half of mesogastric region divided by a median suleus into two lobules. Cardiae region also distinctly divided in the same way. Front less advanced, and lobes less obligue than in M. spinimanus. The lateral tecth and the ehelipeds offer no differences worthy of note. The
ambulatory legs are, however, very distinct. They are shorter than in M. spinimumus. The meral joints are armed on the upper or anterior margin with spiniform teeth, as in that species; the tubercles of the upper surface of the last pair are more depressed. The carpal and propodal joints are ormamented with lobate crests, of which there are three on the carpal joints of the first, second, and third pairs, and two on the propodal joints and on the carpal joint of the fourth pair. The middle crest of the carpal joints (the anterior crest in the last pair) is most prominent, and is composed of three rounded lobes, the interspaces as wide as the lobes. Ambulatory legs hairy, the dactyli densely so.

Abdomen of male with the first three segments tuberculons; anterior margin of each segment, iucluding the coalesced segments, marked by a transverse band of pubescence. Posterior half of sternum tuberenlous; anterior half punctate or pitted.

Itimensions.-Male, type: Length, 17 mmn .; width, 25.6 mm . Female with eggs, station 2812: Length, 8.5 mm .; width, 12.3 mm .

Type.-No. 21580 , U.S.N.M. One male, from Panama Bay, 33 fathoms, station 2796:
Additional specimens.-Panama Bay, $5 \frac{1}{2}$ fathoms, station 2805, two small males; off Hoor Island, Galajagos, 20 fathoms, one female; off Cape St. Lucas, 31 fathoms, station 2829, one male.

## LIPASTHESIUS, nevv genus.

( $\Lambda \varepsilon 1 \pi \omega$, to be wanting; $\alpha 1 \sigma$ 多 $\sigma_{15}$, perception by feeling.)
Allied to Glyptoxanthus, Medseus, and Carpoporus. Basal antennal joint ercluded from the orbit; flayellum and perluncular joints wanting; antero-lateral maryin of the carapace terminating at the angle of the buccal carity.

Carapace in shape resembling Glyptoxanthus; that is, the antero-lateral margin is arcuate, the postero lateral is deeply concave, the anterior half of the carapace is very convex longitudinally, the posterior half is flattened. The antero-lateral margin, however, is thinner than in Glyptoxenthus, and runs obliquely downward to the angle of the buccal cavity, as in Medrens. Front deflexed, forming a projecting lood over the antemmke. Orbits circular. Basal antemmal joint less advanced than the orbital angle; its anterior margin articulates with the lower corner of the front, as does also the imer comer of the lower orbital margin (Plate XLII, fig. 5). The antennte proper, including the peluncular joints and the flagellum. are absent. Only the flat lower surface of the basal joint is exposed to view, and there is no socket to hold an antenna. Epistome with a deep transverse invagination through its entire width. Abdomen of male with the third, fourth, and fifth segments anchylosed. Chelipeds concave on their imer side to fit closely against the carapace. Last pair of ambulatory legs fitting into the postero-lateral sinus of the carapace.
61. LIPÆSTHESIUS LEEANUS, new species.
(Plate XLII, figs. 4, 5.)
Surface gramulate and erorled; color of pollex rumning back on the hand.

Carapace with mesogastric and cardiac regions depressed. Protogastric region forming an elevated protuberance; a similar but smaller protuberance is at the middle of the branchial region; in front of this, two tubercles. Hepatic region inclined. Antero-lateral margin subacute, with about four tubercles at intervals. Surface covered with coarse gramules arranged to form a network or an eroded surface; gastric sutures smooth. Frout strongly deflexed, thin, emarginate, and with a short closed median fissure; lobes oblique, sinuous, bent down at the outer angles to meet the antemal joint. The inferior surface of the crab, excepting the abdomen and the portions against which the legs are applied, is granulous and eroded. Abdomen almost smooth. The palpus of the endognath is folded above the preceding joint, and is only slightly visible in a ventral view.

Chelipeds subergal, thick, outer surface eroded. Fingers gradually curver downward, very rough with granulation; prehensile edges toothed, not gaping; color brown, that of the pollex running back on the hand, furtlier on the inner surface than on the outer. Dactylus longer than the superior margin of the palm. The ambulatory legs are short and are ornamented with gramulations similar to those of the carapace.

Iimensions.-Male: Length, 8.4 mm.; width, 11.4 mm .
Types.-No. 21581 , U.S.N.M. Tro males, from the sonthern part of the Gulf of California, 10 fathoms, station $28 \because 8$.

Named in honor of Prof. L. A. Lee, of Bowdoin College, who was chief naturalist of the Albatross during the cruise around the Horn.

## 62. PILUMNUS SPINULIFER, new species.

> (Plate XLII, figs. (f-8.)

Carapaee rough, nearly nalied; larger hand half smooth; smaller hand entirely rough outside; a sublepatic tooth or spine.

Carapace wide, convex, deeply areolated, surface nearly naked, having only a short, scattered pubescence, not concealing the spiniform gramules covering the surface. These granules are very small posteriorly, but auteriorly they are larger and along the autero-lateral margin many of them are developed into spinules. Median sinus of the front very large and $V$-shaped, forming the inner margins of the two large lobes; the outer margins are also oblique but longer; outer angles of front rectangular; margin thin and granulate. Superior margin of orbit spinulous, inferior margin armed with slender spines; inner suborbital tooth prominent, spinulous, and sharp. Antero-lateral margin
with four spines, bordered by smaller spines or spimules; the greatest interval is between the second and the first or orbital; below this space may be seen a subhepatic spine, similar in character but less produced than the margimal spines. Lower surface of carapace rough and similar to the upper.

Meral joints of chelipeds grambate on outer surface; margins armed with spines and spinules, those of the upper surface increasing in size distally. Carpi spinous. The uper and proximal half of the outer surface of the palm of the larger cheliped is covered with stout spinules, which have a tendency to form longitudinal rows and become smaller and more gramuliform toward the lower and distal margins; the spinules cover the upper surface and extend a little on the imer surface. The smaller palm is roughened on the entire outer surface with spimules or spiniform gramules; upper surface with two rows of spines; imner face gramulons, except near the fingers. Dactyli of both chelipeds a little ronghened near the base. Meral joints of ambnlatory legs armed on the anterior margin with a row of slender spines; posterior margin spinulous; carpal and propodal joints armed above, below, and anteriorly with a row of spines. Legs sparingly pubescent.

Ifimensions.-Male: Entire length, 8.8 mm.; width, including spines, 12.5 mm .

Types.-No. 215s2, U.S.N.M. Two males, off Cape St. Lucas, 31 fathoms, station 2839 .

## 63. PILUMNUS, species.

One young specimen, undeterminel, from Magdalena Bay, Lower California, 81 fathoms, station 2832.

## 64. PILUMNOIDES PERLATUS (Poeppig).

Hepatus perlatus I'oErl'li, Arch. f. Natur., 1836, II, I't. 1, p. 135, pl. wr, fig. 2.

l'ort Otway, Magallanes Territory, Chile.

## 67. XANTHIAS POLITUS Rathbun.

Micropanope polita Rathibun, Proc. U. S. Nat. Mus., 1893, XVI, p. 238.
Janthias politus Rathbun, Bull. Labor. Nat. Ilist. Stato Univ. Lowa, 1898, IV, 1. 271.

Off Hood Island, Galapagos, 20 fathoms, station 2812; off' Cape St. Lutas, Lower California, 31 fathoms, station 2829.
68. MICROPANOPE XANTHIFORMIS (A. Milne-Edwards).

P'anopeus xanthiformis A. Milne-Eipamds, Crust. Reg. Mex., 1880, p. 353, pl. LiII, fig. 4.
Micropanope xanthiformis Ratibun, Bull. Labor. Nat. Hist. State Univ. Iowa, 1898, IV, p. 274.

Off Cape Frio, Brazil, 59) fathoms, station 2762.
69. MICROPANOPE NITIDA, new species.

## (Plato XLII, fig. 9.)

General appearance smooth; frontal lobes rounded; second and fifth lateral teeth reduced; color of pollex not rumning buck on hand.

Carapace broad, convex in both directions; regions very faintly indicated; surface minntely granulate or almost smooth, covered with very minnte puncte, with here and there a larger one. Front inclined, granulate; edge thin, median sinus $V$-shaped; lobes simons, convex for their inner two-thirds. Orbits with two $V$-shaped sinuses on the smperior margin. Lateral teeth five; the first or orbital small and dentiform, the second low and rounded and connected with the first by a shallow sinus; third and fourth large, with arcuate outer and concave inmer margins and acute curved tips; fifth very small and postero lateral. The onter suborbital fissure is deep, narrow at the base, with convex sides; the inner tooth is low and blunt. The second segment of the abrlomen of the male is wide, and at its outer distal corners leaves exposed a very small piece of the stermum. The third segment has a very broad base with angular corners, reaching the coxie of the fifth pair of feet. The penultimate segment is short and widens distally. Terminal segment triangular and blunt.

Chelipeds strong and unequal, with surfaces finely granulate; upper margin of merus gramulate or denticulate. Carpus with a short sharp inner tooth or spine, with a blunt tooth beneath it, and an anterior groove; granules having a tendency to form slight rugæ. Large hand strong, with convex margins; upper surface broad and flattened; in smaller specimens having two blunt crests; fingers bent downward, slightly gaping, with punctate impressed lines; prehensile teeth low. Smaller hand resembling the larger, but abont two-thirds as wide. Color of fingers dark brown, the color line on the pollex rumning obliquely downward from the proximal end of the prehensile margin and parallel to the proximal end of the palm. Ambulatory legs long
and narrow; meral joints with anterior margins spinulous; last two joints with pubescent margins.

Dimensions.-Male: Leugth, 8.1 mm .; width, 11.5 mm .
Types.-No. 21583, U.S.N.M. Two males, eight females. Southern part of Gulf of California, 8 fathoms, station 2824.

Distribution.-Gulf of California, 7 to 10 fathoms, stations 2824 to 282s, inclusive.

## 70. MICROPANOPE AREOLATA, new species.

Carapace arcolate; frontal lobes rounded; second and fifth lateral tecth reduced ; color of pollex rumning back on palm.

This species is closely allied to the preceding, and is associated with it. It is distiuguished by its carapace being slightly narrower, areolate, more distinctly granulate, and slightly pubescent, by the greater roughness of the carpi of the chelipeds, and, above all, by the dark color of the pollex extending well backward and upward on the palm.

Dimensions.-Male: Length, 6.7 mm ; width, 8.9 mm .
Types.-No. 21584, U.S.N.M. Four males, one female. Head of Gulf of California, 11 fathoms, station 3024.

Distrilution.-Gnlf of California, 912 to 11 fathoms, stations 2826, 2827, 2825, 3024.

## 71. LOPHOPANOPEUS MACULATUS, new species.

$$
\text { (Ilate XLII, figs. } 10,11 . \text { ) }
$$

Carpus slightly rough; ambulatory legs slightly cristate; meral joints spinulous; terminal segment of abdomen of male wider than the preceding joint.

Carapace hexagonal, moderately convex, deeply areolated. Surface covered with very fine, depressed, scabrons granules. Front narrow, advanced, thickened, emarginate, with a short, closed, median fissure; margin sinuous, granulate, the onter angle being truncate and obtuse. Lobe between the superior orbital iissures trucate, not produced. Exorbital tooth small; second tooth well marked, though not prominent, roumded; third, fourth, and fifth teeth dentiform, subacute, the fifth a little the smaller. Sinuses separating the second, third, fourth, and fifth teeth continued by grooves on the carapace. The inferior regions of the carapace are grannlous and there is a suborbital tubercle. The imner tooth of the inferior orbital margin is produced, thickened, and obtuse; the outer fissure is large and V-shaped. Proximal angles of third abdominal segment of male acute and overlapping the coxte of the fifth pair of feet. Penultimate segment nearly as long as wide, increasing in width distally. Last segment wider than the preceding aud arcuate.

Chelipeds nearly equal, heavy. Merus trigonal, as broad as long, superior margin denticulate. Carpus slightly rugose, with an anterior groove and two blunt inner teeth, one above the other. The palm of
the larger cheliped is wider than its superior length, and the upper margin is somewhat flattened. The inferior margin of the propodus is slightly sinuous. The surface is punctate with large and small puncte, and finely granulate, the granules becoming larger and rougher on the broad upper surface. The fingers are wide and gape slightly. They are crossed by a few impressed, punctate lines. The dactylus is arched and has a large basal tooth, followed by about seven small teeth. The pollex has about six large teeth. The lesser cheliped is missing in the type male. In a smaller specimen, however, this cheliped is seen to differ from the larger one in being a little narrower, with fingers bent down a little more. All the prehensile teeth are small. The meral joints of the ambulatory legs are narrow, with anterior margins spinulous. The next joint is subcristate, having a deep groove near its anterior margin; the propodi have convex margins.*

Dimensions.-Type male: Length, 7.1 mm. ; width, 9.9 mm . Ovigerous female, station 2831: Length, 4.4 mm .; width, 6 mm .

Color.-In alcohol, the carapace shows ten or twelve dark blue spots; chelipeds reddish, fingers with white tips and teeth; merus joints of ambulatory legs with a dark band at the center.

Types.-No. 21585, U.S.N.M. One male, one female. Southern part of Gulf of California, 8 fathoms, station 2824.

Distribution.-Gulf of California, 7 to 17 fathoms, and Magdalena Bay, Lower California, 12 fathoms, stations 2824, 2825, 2828, 2831, 3002.

## GRAPSILLIDE.

## . 81. QUADRELLA NITIDA Smith.

Guadrellu ritida Smitu, Proc. Boston Soc. Nat. Hist., 1869, NII, p. 288.
Off Cape St. Lucas, Lower California, 31 fathoms, station 2829, two males, two females, one bearing eggs.

Dimensions of Guatrella nitida.

| $\sin$. | T'otal lengeh. | Width. |
| :---: | :---: | :---: |
|  | m.m. | $m m$. |
| Malo. | 8.9 | 9.6 |
| Male. | 5.5 | 5.6 |
| Female with egys | 7.4 | 8 |
| Female | 6.6 | 6.7 |

By Dr. Ortmann this species is united with (o. coronta i)ana. I have not seen specimens of the latter. (). nitida has only one carpal spine instead of the two in coronata. The simses separating the median from the next pair of frontal teeth we more shallow than represented in Dana's figne, and the lateral margins are much more convex.

Allied to (irapsillus; orbital fissure Mosed; sides tro-loothed.
Carapare smooth; wider and sides more areuate than in (irapsillus; furnished with two large teeth on the anterolateral mangin, one at the lateral angle, and one between that and the orbital angle. Posterolateral margins converging. Front broarl, slightly hilobed. Orbits shallow, entire; inner fissme elosed by the union of the lower orbital margin with the front (llate XlII, fig. 13) ; wbit otherwise entire. Peduncular joints of antenne short; the second joint just reaches the lower comer of the front; the thind joint attains the frontal margin. Palatal ridge partially developed, anteriorly obsolete. The anteroexternal angle of the merus of the onter maxillipeds is laterally produced, and the antero-internal angle emarginate (Plate II, fig. 14). Chelipeds mequal, smooth, not enlarged; merns short, margins entire; carpus unispinous; fingers elongate, acute. Ambulatory leg's short, last three joints setose; dactyli rather stout.

## 82. ECT ÆSTHESIUS BIFRONS, new species.

## (Plate NLII, ligs. 12-14.)

Carapace slightly convox in both directions, abont three-fourths as long as wide, antero-lateral margin arcuate, postero-lateral margins sinuous and rapidly converging. Surface smooth, exrept near the front and lateral teeth, where fine granulation may be detected with the lens. Front nearly half the width of the carapace, slightly arenate, almost imperceptibly bilobed, edge thin, retreating at the outer angles. Just above, behind, and parallel to the margin, at a distance of about 0.2 of a millimeter, is a sharp ridge which is slightly intermpted at the median line. Orbit less than half the width of the front; onter angle inconspienons, not advanced beyoud the general ontline of the orbital margin. The tooth at the lateral angle of the curapace is situated a little in front of the middle of the length of the carapace and is subacute. The first tooth of the antero-lateral margin is abont one-third the distance between the orbital angle and the lateral tooth and is obtuse. The abdomen of the mature female is narrow; third, fourth, and fifth segments subequal in length as well as in width; sixth of the same width, but longer; seventh narrower, length and breadth subequal, extremity rounded. l'eluncular joints of antenne short.

Merns of chelipeds extending but little outside the carapace, trigonal. widest near the middle. Carpal tooth large and sharp. Manns with the inner surface swollen towad the proximal end, as in Grapsillus; margins smooth and ronnded; superior margin slightly convex, inferior margin sinnous, that of the pollex being concave. Dactylns longer than the superior margin of the palm. Fingers not gaping, marked with a few lines of punctie; dactylas withont tecth; pollex of the larger eheliped
with one low tooth on basal half and two teeth and a few dentieles on terminal half; in the smaller cheliped the teeth of the pollex are all on the terminal half. The ambulatory legs are of the same nature as those of Grupsillus; dactyli nearly as long as the propodi.

Dimensions.-Ovigerous female: Length, 7 mm ; width, 9.7 mm ; wilth of front, 4.4 mm . exorbital width, 7.2 mm .

Ti.mpe.-No. 215s6, U.S.N.M. One ovigerons female. Off Chatham Island, Galapagos Islands, 45 fathoms, station 2809.

## POR'TUNIDA.

84. PORTUNUS PANAMENSIS (Stimpson).

Achelons pamamensis Stimeson, Amm. Lye, Nat. Hist. N. Y., 18it, X, p. 112.
Neplumis panamemsis A. Milne-EinWarbs, Ctust. Kég. Mex., 1879, p. 21s; not Amphitrite pancixpmis Lockington.
Panama Bay, 33 and 18 fathoms, stations 2797 and 2798.
85. PORTUNUS TRANSVERSUS (Stimpson).

> Achelous transersus Stimbson, Ami. Lyc. Nat. Mist. N. Y., 1871, X, 1, 111.
> Neplumus hrasversus M. Minne-Einwards, Crist. Reg. Mex., 1879, p. 220.

One adult female and one small immature male were taken at station 2800, Pamana Bay, 7 fathoms. The male is about the size of Stimpson's type from Manzanillo, which is not extant, and agrees with his brief description. The adult, however, possesses more strongly marked characters.

This species has, as Stimpson has remarked, the aspect of a Culli. mectes. The carapace is very broald, and the antero-lateral margins are little arched. The depressions separating the areolations are deep; the bramelial ridge is oblique and slightly enrved; the inner banchial lobes are very well marked. The front is little advanced, the fons middle teeth are triangular, bhunt, their tips equidistant, the median pair narrower and more advanced than the next pair. The two teeth above the antemas are well separated from each other and equally advanced, althongh the outer is wider than the inner. The supraorbital simuses are open anteriorly. The eight lateral teeth are subequal, becoming gradually more acute from the first to the eighth. The first or orbital tooth is equally advanced with the outer of the four median frontal teeth. The lateral spine is directed obliquely forward, and is as long as the width of the four preceding teeth. The posterior margin is slightly concave at its middle in the adnlt. The inner snb-
orbital tooth is much more advanced than the tront, and is separated ly a notel from the adjacent orbital margin.

The merus of the left chelipal (the right is missing), is armed on the anterior margin with seven acminate spines; the proximal is very small, the size increasing from the first to the fourth; the fourth, lifth, and sixth are subernal; the distal or seventh spine is longest, and is separated from the next by the greatest interval. In the young, the three proximal spines of the adult are absent. Onter margin termimating in a well-marked spine. The carpus is armed with two spines, a small onter, and an imner spine between two and three times the length of the onter. There are two propodal spines, the posterior in the enstomary position, and a spine near the distal end of the upper margin. The posterior distal angle of the merus of the last pair of feet is armed with a spline.

Dimensions.-Female: Length to tips of teeth, 34 mm ; wilth, 75.6 mm .; width hetween posterior sinuses of anterolateral margin, 55.5 mm . Young male: Length, 11.5 mm . ; width, 26.3 mm .; wilth between posterior sinuses, 18.8 mm .

## 86. PORTUNUS XANTUSII (Stimpson).

From Abroojos Point to Magdalena Ray, Lower California, fod to 48 lathoms, stations 2831, 2834, 2835; Gulf of California.
87. PORTUNUS (ACHELOUS) BREVIMANUS (Faxon).

Achelons spinimanns Faxon, Mem. Mus. Comp. Zool., 18:5, XVIII, p. 2:3 (not Por(ииия sріиішииия Latreillo).
Achelous brerimauns Faxon, Mem. Mus. Comp. Zool., 189\%, XVILI, p. 2\%, in loxt. Near Cocos 1sland, fi6 fathoms.
The characters presented by a series of specimens from the Pacitie seem to justify their specific separation from $I^{\prime}$ 'spinimanus. P. Inerimanns is less pubescent amd has a much more moven surface; the anterior branchial ridge is more strongly arched forward and the two short branchial ridges are more oblique than in typical spinimanus. In brevimanus the median lobe of the superior orbital margin is strongly producel at its outer angle; in spinimanus this angle is advanced very little, if at all, heyond the inner. The inner eapal spine of the chelipeds is noticeably longer, and also the merns joint of the swimming leet, than in spinimanus. Some of the specimens collected are mature, but all are smaller than the type. None have the small spine at the distal end of the palm, and only one spine is present at the posterior distal corner of the merus of the swimming feet.

Off Hood Island, (Galapagos, 20 and 40 fathoms, stations $\geq 812$ and 2813; Albemarle Island, Gatapagos.

Proc. N. M. vol. xxi- 38
88. PORTUNUS (ACHELOUS) ANGUSTUS, new species.

## (Plato $\mathrm{XLIV}^{*}$, fig. 2.)

Front adranced, s-toothed; lateral teeth alternately large and small; lateral spine only slightly longer than seventh tooth; a spine at posterior distal angle of merus of swimming feet.

Carapace narrow, pubescent except upon the transverse granulated lines; in shape resembling $I^{\prime}$. orrlwayi (Stimpson). Front advanced; four middle tecth subacnte, the outer pair broader at base than the immer, and separated from the inner pair by wider sinuses than the median sinus, and from the supra-antennal angle by a deep V-shitped sinus. Supra-antennal lobe bidentate; teeth acnte. Antero-lateral teeth alternately large and small, the last tooth or lateral spine very little longer than the seventh. The inner suborbital tooth is acute and equally advanced with the second pair (reckoning from the middle) of frontal teeth; there are no teeth on either side of the outer orbital fissure.

The merus of the cheliped of the type specimen, a femate, has four spines on its imer margin, graduated from a large one near the distal end to a small one near the ischinm; a very small spine on the outer margin at the distal end. Carpus with a small external distal spine and a long inner spine reaching, when the arm is flexed, to the spine next to the smallest on the merus. The hand has two large spines, one next the earpus and one on the superior margin at one third its length from the dactylus. The ridges on the carpus, propodus, and dactylus are very coarsely granulated with acorn-shaped granules. The depressions are pubescent. The exterosuperior surface of the merus is crossed by a longitudinal ridge. The inferior margin of the merus of the left natatory foot is armed with a sharp spine near the distal end; on the right foot there are two smaller spines in the same position.

Color.-Although this crab has been for a long time in alcohol, it seems to be of a reddish hue. The basal half of the fingers is red, the next quarter is white, the remainder is brown, except the tips, which are white.

Dimensions.-Female : Total length of earapace, 25.05 mm . ; total width, 37.2 mm . ; width between the last simuses, 33.5 mm ; exorbital width, 21 mm .

Type.-No. 21587, U.S.N.M. One female; off Hood Island, Galapagos, 20 fathoms, station 2812.

This species has considerable resemblance to Charybrlella (=Cronius), but the basal antennal joint is not so strongly produced as in that genus. It can also be told by its narrower carapace and frontal teeth, and few spines on the hand.
89. PORTUNUS (ACHELOUS) ORDWAYI (Stimpson).

91. PORTUNUS (ACHELOUS) MINIMUS, new species.
(Plate NLIV, fig. 3.)
Front eight-toothel; sccond, fourth, and sixth lateral tecth rechueed; lateral spine twice as long as eighth tooth; merus with four spines on anterior magin; spinules at posterior distal margin of swimming fect.

This is a very small species, as adults average about 15 mm . in width. Surface pubescent; ridges fairly well marked; the inner portion of the transverse branchial ridge is advanced to a point in line with the sixth lateral teeth. Front very wide; four median teeth, obtusely rounded, separated by rounded sinuses; the median pair of teeth narrower than the lateral and more advanced; the lateral sinuses as deep as the median and much wider. Supra-antennal teeth less advanced, two in number, subacute, separated by a shallow sinus. Of the superior orbital fissures, the inner is in narrow slit, the outer is V-shaped. The outer orbital tooth is less advanced than any of the frontal teeth, is rather large, and obtusely rounded. The other lateral teeth are acute. The second, fourth, and sixth are smaller than the others, and themselves diminish in size in the order named. The lateral spine is curved upward and forward and equals in length the width of the two preceding teeth. The inner suborbital tooth is produced to the line of the second pair of frontal teeth. Outer sinus of the suborbital margin $V$-shaped.

Merus of the chelipeds with three anterior spines, of which the proximal is the smaller, the others subequal; posterior margin terminating in a small spine. Carpus with a small outer spine and a large inner one about three times the length of the outer. Manus with two spines, one next the carpus and one near the distal end of the upper margin. Posterodistal margin of merus of swimming feet armed with fine spinules, but without a single long spine.

Dimensions.-Male, station 2827: Total length, 10.2 mm ; width, 17 mm ; width between last antero-lateral sinuses, 14.1 mm ; exorbital wulth, 10 mm . Female, station 2826: Total length, 9.4 mm ; width, 15.7 min .; width between last sinuses, 12.8 mm .

Type.-No. 21588, U.S.N.M. One 'adult male, three adult females, one ovigerous. Station 2827,10 fathoms.
Habitat.-Southern part of the Gulf of California, $9 \frac{1}{2}$ to 10 fathoms, at the following stations: 2826, one ovigerous female; 2827, type locality; 2828, one young male, six adult females (three ovigerous).

OVALIPES, nevv genus.
(From ovalis, oval, and per, foot.)
Platyonichus Latreille, 1825, part, not Platyonichus Latreille, 1818. Type, I'latyonichus ocellatus (Herbst) Latreille.
In 1897, ${ }^{1}$ I showed that Platyonichus (Latreille, 1818) is synonymous with Portumnus (Leach, 1814), both having as type the species Cuncer lutipes Pemant. At the same time I suggested that Kaiva (Mac Leay, 1838) could be used for the species ocellatus and bipustulatus, which for many years have been included in or have represented the genus I'latyonichus. It has since been brought to my attention that the type of Taiva, A. pulchella Mac Leay, is more nearly related to Portumnus than it is to the species ocellutus and bipustulatus. For these last, therefore, I an obliged to propose a new name. Ovalipes differs from Portumnus and Xuiva in liaving the last joint of the fifth pair of feet broadly oval, rounded at the extremity, instead of lanceolate and acute; the basal joint of the antemulee advanced and visible in a dorsal view between the frontal teeth; the chelipeds elongate; the abdomen of the male oblong instead of narrow triangular.
98. OVALIPES BIPUSTULATUS (Milne-Edwards).

I'latyoniehur bipustulatus Minne-Eibwards, Mist. Nat. Crust., 1831, I, p. 437, pl. xvif, figs. 7-10.

## ACANTHOCYCLIDA.

## Genus ACANTHOCYCLUS.

A study of the specimens of Acanthocyclus in the U. S. National Museum, collected by the Albatross and others, and in the Museum of Comparative Zoology, indicates that there are three distinct species on the west coast of South America. The first species and type of the genus is A. gayi Milne-Edwards and Lucas, 1843. The existence of a second species was first recognized by Strahl in 1862, who unluckily applied to it the name A.gayi, giving to the form which is the true gayi a new name, A. villosus, which therefore becomes a synonym. The second species-that is, the A. gayi of Strahl-was later taken by the Mayenta on the west coast of Patagonia, and again named " $A$. gay" by Targioni-Tozzetti.

[^2]Specimens of $A$. fayi in the U. S. National Mnsem have been identified by comparison with a type in the musemm of the lhiladelphia Acarlemy of Sciences. Professor Stmany, of the musenm in Vienna, has kindly determined as the same species the type specimen of $A$. gayi Heller, 18(5\% ( $=$ I'la!nusctes clatus Heller, 18tiy). The existence ol' a third species was discovered by Dr. Walter Faxon, who torned his notes and specimons over to me. 'The general appearance of the three species is muld the same. The differences are constant and can best be expressed in the following table:

## (harterteristies of specics of Acauthocyclus.

Port Castries, St. Lucia.

## 1'ALICIDA.

105. PALICUS ZONATUS Rathbun.

Cymopolia zonatu kathbinn, Jroc. U. S. Nat Mns., 1893, XVI, 〕. 259.
l'alichs zomalus Ratimbin, Proe. Biol. Soc. Washington, 1897, XI, p. 94.
Sonthern part of Gulf of California, 8 to 10 fathoms, stations 2824, 2827 , 2820; off Cape St. Lucas, 31 fathoms, station 2829.
106. PALICUS LUCASII, new species.
(Plate X1,III, lig. 2.)
Length of sceond ambulatory ley less than twiee the width of the carapues. Abdomen aul sternum not conspicuously eristate. Antero-lateral teeth taco, brsides the orbital. Anterior margin of second and third ambulatory leys terminating in an acute or subaeute tooth, not spiniform.

Allied to ' $I$. dentatus, faxoni and relternatus of the West Indian region.

Carelpace broad, subpuadrate. The clusters of tubercles on the sur face are well marked and distinct from one another; those on the cardiac and intestinal regions have a short transverse crest. The surface between the clusters is covered with gramules barely visible to the naked eye. Frontal lobes or teeth four, the median pair small and rounded and separated by a narrow rounded sinus more than twice as deep as those dividing the median from the lateral pair; these last have an oblique areuate onter margin. The preorbital lobe is slightly bilobed by an indentation at its summit. The two supraorbital teeth are trian gular and snbacute. The postorbital tooth is directed forward; behind it, on the lateral margin, are two large acute teeth, with straight inner margins; outer margins slightly areuate. These teeth are followed by one or more a lenticles. The crest above the posterior margin is cut into four long and three short transversely linear tubercles. Suborbital lobe truncate, not advanced, and separated on either side by a $V$-shaped fissure. The lobe at the angle of the bnceal cavity is triangular, and in a ventral view only partially obscures the truncate inner suborbital lobe. Basal joint of the antenna cut by a deep U-shaped sinus into two lobes, the imer and inferior small and tuberculiform, the outer and superior broad and lobiform.

The riglit cheliped of the male is very heavy. Merus spinnlons. Carpus with about four superior spines and a number of spmules, an inuer spine, a spinulous antero-internal crest, a right-angled antero-
external crest. The proporlus is very large; its width is nearly equal to its superior length, and its thickness is about half its superior length; it is surmounted by a donble crest of irregular spinulous spines or tubercles; inner and outer surfaces granulous, the granules of the onter surface tending to collect in two longitudinal bands, one median, the other at the lower margin. Fingers gaping slightly, for two-thirds of their length deeply grooved, margins nneven but not lentate; pollex not deflexed. The left cheliped is missing in the adult males. In the immature male the right cheliped is much less strong than in the adult; the left propolus is about half as wide as the right. The same is true of the female; the fingers are proportionately longer than in the male, not gaping; poliex somewhat deflexed. Ambulatory legs of moderate length. Meral joints broad, coarsely gramuate; terminal tooth of anterior margin in the first pair acute and spiniform, in the second and third pairs acute or subacnte. Proximal lobe of anterior margin of carpal joints rounded; terminal teeth acute, excepting the one on the anterior margin of the first pair, which is obtnse. Dactyli with simons posterior margins. Last pair of feet reaching a little beyond the merus of the preceding pair.

Dimensions.-Male: Length, 13.5 mm. ; width, 15.7 mm ; length of right propodus, measured on lower margin, 10 mm . ; on superior margin, 6 mm ; width, 5.4 mm .; thickness, 3.2 nm . Female: Length, 11.3 mm.; width, 13.1 mm .

T'ypes.-No. 21590, U.S.N.M. Three males, four females, from off Cape St. Lucas, 31 fathoms, station 282!.

## OOYPODIDK。

107. EUCRATOPSIS MACROPHTHALMA, new species.
(Illate XLIII, figs. 3, 4.)
Carapace and orbits very wide; egles long; three sulvequal intero lateral teeth.

Carapace wider then in E. elata (A. Milne Edwards); regions distinct. Carapace very convex longitudinally; transversely nearly level for its middle two-thirds, deflexed toward the margins; marginal teeth directed obliquely upward. Front about one third the width of the carapace; lobes slightly convex. Orbits wider and eyes longer than in E. clute; superior margin of orbit sloping lackward and outward. Antero-lateral teeth three, including the orbital, aente, curved slightly forwarl; postero-lateral margin with a slight tooth or noteh. The earapace has more the appearance of Eurypiax nitidus Stimpson, but the antennar are not excluded from the orbits, as in that genus.

The merus of the right cheliped (the left is wanting) is granulated toward the margins, which are marmed. Carpus finely granulated, with an anterior snbmarginal sulens and a short blunt mner tooth, which is continued anferiorly in a blunt prominence. The palm is slightly
margined above and below；the fingers are broad and llat，not gaping， with a narow grambate border on the outer edges；prehensilo margins erenate，with a slightly larger lohe near the base of the dactylns，and a thred－lobed prominence at the hase of the pollex．Lower margin of the propodus slightly simoms．
（＇olor．－la alcohol，the carapace is marked with patehes of dark blue．
Dimensioms．－Malo：Length， 3 mm．；wilth， 5.1 mm ．
T？fиe－No．21501，U．S．N．M．Ono female，from Panama Bay， 51 d fathoms，station 280 ．

This species is plared provisiomally in Eucrotopsis．It may represent a distinet gemms，which it is perhaps not advisable to deline until the male is known．

## 108．SPEOCARCINUS GRANULIMANUS Rathbun．

Speocarcinus ！ramulimanus Lathinun，I＇roe．IJ．S．Nal．，Mus．，189：3，XV1，p．242．

## 109．GERYON QUINQUEDENS Smith．

```
    1f, 1b, ב.
```

Off Cape lirio，Brazil， 671 fathoms，station $\because 76$ Bin．Ono small male，$^{2}$ which differs fiom North $\Delta$ thantic specimens only in tho larger median teeth of the front．

11．CHASMOCARCINUS TYPICUS Rathbun．
Chesmocarcinns t！ppichs Listubun，Bull．Labor．Nat，Hisl．Stato Univ．Lowa，

Off Cape lrio，Brazil，folathoms，station 2762．
11．CHASMOCARCINUS LATIPES，new species．
（Plate XI．111，lig．5．）
Orlits direrted abliguely firmard：stormam atud ablomen of femate smooth aml pametute：ambulntory le！！s wide．
dength of carapare about two thirds its posterior width．Front and orbits less than one－half the width of the carapace．Surface covered with large punctar which tend to coalesce；grambate on the posterior half and toward the margins．The branchial region is separated by very deep longitudinal impressed lines from the cardiac and mesogas－ tric regions，by shallow depressions from the intestinal region，and by two pits from the hepatie region．The antero－lateral margin is distinet， though bhat．Front very marow and faintly bibobed；side margins obligue．Orbit nearly as wide as the front；the superior margin is slightly conc：ave and direeted oblignely forward and outward．The eye－stalk is stont and carved as seen from in front and hapers grad－ mally to the cornea．The groove below tho hopatie region is similar to that in（＇．！！piens．The sternm and abdomen of the female are smooth and punctate．

The chelipeds resemble those of the female of C. typicus. The caupus, however, is nearly square, the propodus is less arched, and the fingers taper regularly to the tips. The propodus has a line of gramules on its lower margin. The margins of the chelipeds are fringed with hair, which is longest on the upper margin of the merns, where there is a fringe on the proximal half and a tuft near the distal end. Ambulatory legs shorter and broader than in O. t!pirus, hairy, especially on the margins. The dactyli of the first three pairs are similar, broad and thin; in I late XLIII, fig. I, the finll width of the dactyli of the first and second pairs is shown; those of the third pair are viewed oblignely; in the fourth pair the dactyli are narrow and recurved, as represented in the fignre.

Cobor:-In alcohol the carapace is a bluish gray, chelipeds pate pink, ventral side of erab and ambulatory legs rust colored.

Dimensions.-Female: Length, 12.5 mm .; width, 17.8 mm .
Type- - No. 21592, U.S.N.M. One female from Magdalena Bay, Lower Ualifornia, 51 fathoms, station 2833.
112. OCYPODE ARENARIA Say.

Ueypode aremarius SAY, Jour. Phila. Nead. Sici., 1817, I, p. 69.
Port Castries, St. Lacia; Bahia and Abrolhos 1slands, Brazil.
113. OCYPODE GAUDICHAUDII Milne-Edwards and Lucas.

Panama; Chatham Island, Calapagos.
114. UCA GRACILIS Rathbun.

Golusimns !racilis Ratimun, Irue. V. S. Nat. Mne., 1893, XV1, p. 24.
Pichilinque Bay, Gulf of California.
It is possible that this species is identical with Gelasimus crenulatus Lockingtom, I877, and this beliof is held by Mr. S. J. Hohmes, who has examined specimens labeled (f. crenulatus in Lockington's collection; the types are probably not extant. In the absence of positive proof I hesitate to restore the earlier name. Uca gracilis is a very distinct species from U. stenoducty/u (Milne-Edwards and Lueas) and from the varions forms which have been mited under the name $U$. vocator. Its noarest ally is Uer specioss (Ives).
115. UCA STENODACTYLUS (Milne-Edwards and Lucas).

Gelasimus atrmodactylus Mante-Edwards and Lucas, D'Orhigny'n Voy: l'Amér. Mérinl., [813, VI, Pt. 1, p. 26; 1817, 1X, pl. xi, fig. 2.

Sesarmu roberti Mune-Edwards, Amm. Sci. Nat., 1853 , 3 d ser., XX, p, 182 (148).
I'ort Castries, St. lillcia.
124. CHASMAGNATHUS GRANULATUS Dana.

Chasmagmathus gramulatus Dane, I'roc. Acad. Nat. Sici. Philit., 1851, V, p. 2:5; Crust. U. S. Expl. Exped., 1852, I, p. 364 ; 1855), pI. xxifi, fig. 6.
Montevideo, Uruguay.

## 125. PLAGUSIA TUBERCULATA Lamarck.

I'lagusia tuberculuta Lamarce, Hist. Nat. Anim. sims Vort., 1818, V, p. 217.
Panama; one young male.
This specimen is a trne tuberculata; the lobe above the bases of the ambulatory legs is not dentated, and the terminal segment of the abolo. men is broadly semioval and rounded at its distal extrenity.

## PINNOTHERIDA.

## 126. PINNIXA CALIFORNIENSIS Rathbun.

Pinuixa califormicusis Ratmbun, Proc. U. S. Nat. Mhes., 1893, XV1, p. 249.
Magdalena liay, Lower California, 51 fathoms, station 2833; one male, without feet.
127. PINNIXA BREVIPOLLEX, new species.

## (I'late XLAII, lig. 6.)

Poller a short spine; dactyl transverse; a transverse cardiac cresl.
Carapace meven, punctate, the gastric and hepatic regions bounded by very deep furrows; cardiae region high and crossed by a transverse erest, surmounted in the male by two triangular tubereles, compressed from before backward, and subacute; in the female the crest is lower, blunt, and divided in the middle by a very shallow sinus. Froutal and hepatic regions granulated. Subhepratic region with a small depressed area or tuberele surrounded by a deep groove. Antero-lateral margin of the branchial region armed with from four to six distant blunt spimules begiming at the lateral angle and followed near the hepatic region by smaller tubercles or gramules. Inferior margin of the carapace granulated. The margins of the frontal lobes extend obliquely backward from the middle. The antennat exceed the width of the front. The sides of the male abdomen from the third to the fifth segments, inclusive, converge regularly; those of the sixth joint are still more convergent, joint very short; terminal joint narrowest, broader than long, rounded. The last two joints of the palpus of the maxillipeds are oblong; the terminal joint is articulated near the base of the second joint, and overreaches it considerably, overlapping the sternum and touching the tip of the abdomen in the male.

Chelipeds wanting in the male; in the female they are monodactyl. Propodus very broad, flattened, increasing in width distally, its greatest width equaling the superior length; superior margin slightly convex; lower margin slightly convex for its proximal two-thirds;
deflexed for its distal third and terminating in a short digital spine which serves as the pollex; distal margin transverse and armed with two tubereles, one near the insertion of the dactylus and the other at the middle. Dactylus transverse, a tubercle at the middle of the prehensile margin which fits against the margin of the propotus. The first and second pairs of ambulatory legs are narrow, the second the longer and larger and reaching to the extremity of the propodus of the third pair. The merus of the third pair is very little dilated at the middle. The fourth pair reaches the middle of the carpus of the third pair.

The entire surface of the crab is covered with a dense pubescent coat.

Dimensions.-Male: Length, $\overline{2} . \overline{\mathrm{n}} \mathrm{mm}$.; width, 11 mm . Female: Length, 6.6 mm . ; width, 12.5 mm .

Types.-No. 21593, U.S.N.M. One male, two females. Off Gulf of San Matias, Argentina, 4s fathoms, station 2768.
This species bears appareatly considerable resemblance to the littleknown Pimnixa monodactylus (Say), ${ }^{\text {' wheh }}$ wh a narrower species.
128. PINNIXA AFFINIS, new species.

> (Plate XLILI, figs. 7-9.)

Lorer margin of palm of female conrex; pollex short; posterior margin of merns of third rmbulatory ley armed with spimules or small spines.

Allied to I'. culiforniensis Rathbun, with which it might easily be confonnded.

Female.-Carapace broader than in californiensis, regions distinctly indicated, cardiac region crossed by a blunt, transverse, bilobed crest; surface punctate, the punctie largest on the branchial regions. A grambate line marks the antero lateral border of the branchial region. The front is not advanced beyond the line of the subhepatie region. The third joint of the palpus of the maxillipeds is articulated near the proximal end of the imer side of the second.
The chelipeds are smooth and pubescent; lower margin of palm convex; pollex short, very broad and deflexed, its prehensile edge irregularly dentate, terminating in a short, acnte spine; the dactylns has a large tooth at one-third the distance from the base; the fingers when closed do not gape. The first two pairs of ambulatory legs are slender, the margins of the propodal joints subparallel; the first pair reaches to the end of the propolus of the second; the second to the end of the propodus of the third. The third leg is the broadest; the merus is very hairy along the margins; the posterior margin is armed with spinmles, those near the middle being larger and spine-like; anterior margin granulons. The fourth pair of ambulatory legs reaches about

[^3]to the end of the carpus of the third pair; the propodus is narrow, as in the first and second pairs.

Dimensions.-Female: Length, 3.4 mm. ; width, 7.3 mm .
Type.-No. 21594, U.S.N.M. One female, with eggs. P'anama Bay, 26 fathoms, station 2803.
129. PINNAXODES HIRTIPES Heller?
(Plate XLIII, figs. 10, 11.)
Pimnaxodes hirtipes Heller, Reise Norara, Crust., 1865, p. (68, pl. vi, fig. 2.
Port Otway, Chile; one male.
This specimen agrees fairly well with Heller's description and figure, but it seems to me that this species is distinct from $P$. chilensis (MilneEdwards) with which it has been united. In the Albatross specimen, which is the only one that I have seen, the carapace is very convex, broader than long, thin, but not soft and yielding, without the longitndinal sulci from the orbits, as figured in $I$. chilensis by Milne-Edwards and Lucas. On either side of the gastric region there is a very short longitudinal groove or dent (about half a millimeter in length). The second segment of the abdomen is more than twice as long as the first. The abdomen tapers regularly from the third to the fifth segment, inclusive; the sixth has concave lateral margins. The last three segments of the maxillipeds resemble those figured by Heller. The under surface of the body and also the legs are pubescent; and the latter are margined with long hair. The fingers of the chelipeds are wide and very little gaping. The ambulatory legs are narrow, much like those figured by Heller, but the meri are proportionately longer, which may be due to the difference in sex.

Dimensions.-Male: Length, 7 mm ; wilth, 7.6 mm .

## TETRIAS, nev genus.

Carapace transverse, hard; palpus of maxilliped with joints end to end; ambulatory legs of the second pair the longest.

Carapace transverse, subquadrilateral, with antero-lateral angles rounded; high, sides steep; posterior two-thirds flattened, anterior third deflexed. Abdomen of adult female suborbicular, at base only half the width of the sternum, tip advanced as far as the extremity of the ischium of the maxillipeds. Maxillipeds very large, with the ischium well developed, the merus enlarged at its middle; propodal joint oblong, broadening at the distal end; terminal joint similar and attached on the inner portion of the distal margin of the preceding. Chelipeds stout; fingers longitudinal. Ambulatory legs diminishing from the second to the fourth pair, which is very small; first and third pairs subequal.

This genus resembles Parapinnixa, Pinnaxodes, and Pimnotherelia in having the maxillipeds with a palpus of three joints placed end to end.

It diflers from the first named in the very large size of the palpus and in the relative lengths of the ambulatory legs; from the second in the transverse flattened carapace, as well as in the larger palpus; from the third in the broader carapace and buccal cavity and narrower front.
130. TETRIAS SCABRIPES, new species.
(Plato NLIII, figs. 12-14.)
Curapace setose; legs rou!h with tubereles anul spinules.
Carapace covered with a sloort, dense coating of coarse, dark setie, beneath which the surface is punctate; regions indicated by impressed lines and pits, the deepest that between the eardiac and gastrie regions; onter marein of hepatic region bearing a tuberele. l'ront projecting very slightly beyond the anterior margin of the carapace, and bent down to form the roof of the antennular cavities, as in Pimixa. Abolomen of female fringed with long lair. Maxillipeds bearded with long silken lanirs, most noticeable on the margins of the last two palpar joints, and in a transverse line on the merns.

The outer surface of the merus of the chelipeds is triangular and as broad as long; its npper and lower margins are rongh with small spines or spinules. The inner angles of the carpus are rectangular; each angle is armed with two or three short spines. Palms broad, with convex subacnte margins, and covered with sharp tubercles arranged in longitudinal lines. These tubercles extend to the tips of the fingers, which are finely dentate along their prehensile edges and fit closely together. The meri of the ambulatory legs are narow, with subparallel margins. The first ambulatory leg reaches to the end of the propodus of the second pair; its merus has the inferior margin denticulate, the superior margin with three spinules at its proximal end; the carpus and propodus short and broad; the dacty!us stout and half as long as the propochis. "The seeond or longest ambinatory is a little longer tham the width of the carapace; its merus has a spimule at the proximal end of the upper margin, and the lower margin is somewhat roughened; the carpins and propodus are proportionally narrower than in the first leg. The third ambulatory reaches about the middle of the propodus of the second, and the joints resemble those of the second pair, but are unarmed. The last leg is much reduced, and reaches a little boyond the middle of the merns of the preceding pair; the joints are proportionally rather broad; the lower margin of the ischimm and merus is armed with spines and spinules; dactylus very small. The legs are covered with setar like those on the carapace, and fringed with hair.

Dimensions.-l'emale: Length, $6 \mathrm{mmı}$; anterior width, 9.2 mm . greatest wilth, 9.2 mm .

TIMpe--No. 21595, IJ.S.N.M. One egg-bearing female, southern part of ciull of California, $9 \frac{1}{2}$ fathoms, station $28 \%(6$.

134. CALAPPA SAUSSUREI, new species.
(Plnto NLI, lim. (i.)
Carapuee slightly brouder than lony, greatest widlh "t the antepenult tooth of the leteral margin; tulereles prominent.

This species is analogons to O. angusta A. Milno-Edwards of the West Indies in its narow earapace, but whereas in C. angusta the greatest width of the carapace is midway of its length, in sumssurei the greatest width is between the antepenult teeth of the lateral margin. Ciurapaco slightly broader than long, almost circular, exclusive of the posterolateral limb, which has a subrectangular ontline; two well-marked grooves form the lateral boundaries of the eardiae and gastric regions. 'Tubereles of the carapace conical, and disposed as follows: Gastric region with two large median and two smaller lateral in advance of these, and about eighteen very small; cardiac with one contral larger survounded by six smaller; brauchial region with about tifteen largo and more than that number of small; intestinal region with six in two lines diverging posteriorly; hepatic region with five or six very small depressed tubercles. The surfice of the tubercles is densely gramulated; the space between them is covered with isolated grannlos. Margins of the front slightly raised; only a shallow groove separates the superior border of the antemmary fosse from that of the orbits. The lateral border of the carapace has five or six sinall tubereles on Proc. N. M. vol. xxi-39
the hepatic region; on the bramehial region fom to six larger tubereles; behind these are five broad, acute teeth, increasing suecessively in size, the third most prodnced ontwandly. On the posterior margin there are two teeth noxt to the postero lateral, followed by a tubercle; the imermost tooth is the smaller; they reach a little behind the level of the postero-lateral tooth, but not so far as the middle portion of the posterior margilu.

The cheliperls have a surface similar to that of the carapace-that is, there are many large tubercles, irregular in size and disposition, and the intervening space is covered, though not crowded, with granules. The manns is considerably longer than high; the four distal teeth of the upper margin are about equally advanced; the immovable finger is very slightly deflexed.

Dimensions.-Male: Length, 20.5 mm.; width at middle, 23.6 mm ; greatest width, 2.4 .4 mm . width at postero lateral angles, 22.9 mm .

T'ype.-No. 2159(i, U.S.N.M. One male. Southern part of Gult of Oalifornia, $26 \frac{1}{2}$ tathoms, station 2823 .

Additional specimen.-One yomg specimen was taken near the type locality on a subsequent cruise, off San Josef Island, 40 fathoms, station 2998.

## MA'TU'TIDA.

137. HEPATUS KOSSMANNI Neumann.

Panama Bay, 7 and 1.1 fathoms, stations 2800 and 2501.
138. HEPATUS LINEATUS, new species.

> (I'late N1.1V, tig. I.)

Carapace narrow and high; hepatic region smooth; front adranced, thick, truncote; first to sixth segments of ablomen of mate tuberculate.

This species iliffers from all others in its narrower carapace, which is very strongly arched, the height being abont one-third the width. As is customary in the genns, there are eight clusters of tubercles. The three posterior groups consist of one large tuberele and from eight to
twelve smaller ones, forming subtriangular patches, with the large tubercle on the anterior margin. The median gastric claster is similar, with the addition of three small tubereles in front of the triangle. The anterior branchial chaster consists of two or three coalesced tubercles, anterior to which there is a line of from eleven to fonteen tubereles extending obliquely backward and outward. The lateral gastric clusters have a large central tubercle with about eight posterior and lateral smaller tubereles, and anteriorly a donble arcuate row containing about fourteen tubercles. Hepatic region smooth. Antero-lateral margin edged with prominent tuberclos, which form about thirteen shallow lobes. Postero-lateral margin very concave, the anterior portion thickened amb bearing a double row of tubercles. The tooth near the posterior margin is much more pronomeed than in 11 . chilensis of equal si\%e.

Front advanced considerably beyond the outer orbital angles, trumcate, thickened, having a double row of depressed tubercles and a short closed metian tissure. The suborbital rogion is similar in shape to that of II. chilensis, althongh its lower margin in a front view is more strongly arched. The abdomen of the mate is narower than in chilensis; the second segment has a tramsverse row of five to seven tubereles, the third it traisverse row of six tubereles, the fourth segment a row of four less prominent; on each of these segments there is a tuberele at the outer distal angle; fifth and sixth segments with a transverse ridge terminating at either end in a low tuberele. Althongh the third, fourth, and fifth segments of the abdomen are anchylosed, the divisions between them are indicated by deep grooves. Stermm coarsely tuberculate.

The five inferior rows of tubereles on the onter surface of the propodus of the chelipeds are composed of large tubereles, bringing the rows nearer together than in related species. On the superior margin there are four tee th, the two proximal being the larger. The propodal joints of the ambulatory legs are shorter and hroader than in $I$. chilensis and II. Kossmanni ; dactyli densely pilose.

Color.-The color of the two specimens of this species differs markedly. In one there are red lines encireling romad or ohlong areas, which tonch one another; in the other the lines border narrow stripes, forming transversely arcuate bands across the carapace, except on the posterior portion, where the patches are more irregular. The specimens have been too long in alcohol for one to detemine whether the space inclosed by the red lines is the same color as that withont or not.

Dimensions.-Male: Length, 17.6 mm .; width, 22 mm . Male: Length, 16.7 mm .; width, 20.2 mm .

TIypes.-No. 21597, U.S.N.M. Two males. Off Abreojos Point, Lower California, $5 \frac{1}{2}$ fathoms, station $28: 35$.
139. OSACHILA LEVIS, new species.

Shape resembling O. tuberosa; surface smooth.
The shape of the carapace is almost exactly like that of $O$. tuberosa Stimpson. The character of the surface is, however, strikingly different. While the protuberances of the carapace are placed similarly to those of tuberosa, their surface is entirely smooth and punctate, without suggestion of tuberculation or erosion as in tuberosa. The lateral angle of the carapace is farther back in levis than in tuberosa, the postero-lateral margin is less concave, and the posterior portion of the carapace wider. The protuberances of the dorsal surface are also more depressed, especially noticeable in those of the gastrie region. The inferior surface is roughened as in tuberosa, although the tubercles are less confluent than in that species. The same is true of the outer surface of the chelipeds. The ambulatory legs are shorter than in tuberosa.

Dimensions.-Fenale: Median length, 19.1 mm ; width, 21.4 mm.
Type.-No. 215!98, U.S.N.M. One female with eggs. Off Cape St. Lucas, 31 fathoms, station $23: 9$.

## LEUCOSIID.E.

140. SPELCEOPHORUS ELEVATUS Rathbun.

Spelwophorus eleratus Ratmbun, Bull. Labor. Nat. Hist. State Univ. Iowa, 1898, IV, p. 290, pl. 1II, fig. 1.
Off Cape St. Roque, Brazil, 20 fathoms, station 2758.
141. EBALIA CRISTATA, new species.

> (Plate XLIV, fig. 5.)

Carapaee oçtagonal, tubereulate, posteriorly bilobed; fiont entire; chelipeds eristate; third to fifth segments of abdomen coalescerl; penultimate sergment spiner.

Carapace thick, octagoual; leugth and breadth subequal. A median ridge extends from the front backward to the intestinal region. Frout truncate. Antero-lateral margin with two shallow lobes; below the margin are two teeth, one pterygostomian, the other branchial. Lateral angle of the carapace acute; from this point the postero-lateral margin is straight for half its length, the straight portion terminating in an acute angle. From this angle to the posterior margin the posterolateral margin is concave. Posterior margin distinctly bilobed. In a side view the intestimal region is seen to have a perpendicular posterior margin. Anterior third of the carapace depressed. From the median gastric ridge au elevated area extends obliquely toward the anterior half of the postero-lateral margin; this is irregularly tumid. The entire surface of the body and legs is covered with tubercies. The third, fourth, and fifth segments of the abdomen of the male are coalesced. The sixth segment has parallel sides and is longer than wide, and
bears at its proximal end a strong acute spine projecting obliquely backward. Terminal segment long and narrow.
Merus of chelipeds cylindrical, length less than twice the thickness. Carpus, propodus, and dactylus with a thin, acute crest. Palm swollen, lower margin very convex; fingers as long as the palm, not gaping. Ambulatory legs armed above with small spinules.

Dimensions.-Male: Length on median line, 9.6 mm .; width, 10 mm .
Type.-No. 21599, U.S.N.M. One male. Off Abreojos Point, Lower California, 48 fathoms, station 2834.

## 142. LITHADIA CUMINGII Bell.

Lithadia cumingii Bele, Trans. Limı. Soc. Loudon, 1855, XXI, p. 305, pl. xxxiri, ligs. 6, 7.
Sonthern part of Gulf of California, $26 \frac{1}{2}$ fathoms, station 2823, one female; Magdalena Bay, Lower California, 51 fathoms, station 2833, one young female.

Bell's description and figures were made from males only. The females are much broader than loug, but the elevations and depressions are arranged as in Bell's Plate XXXIII, fig. 7; the ridges are acute; the tubercles in the depressions are flat-topped.

Dimensions.-Adnlt female: Eutire length, 11.7 mm ; width 14 mm . Young female: Entire length, 7.5 mm ; width, 8.6 mm .
143. PERSEPHONA TOWNSENDI Rathbun.

Myra townsendi Rathbun, Proc. LT. S. Nat. Mus., 1893, XVI, p. 255.
Panama Bay, 7 and 14 fathoms, stations 2800 and 2801.
Persephona and Myra are separated by too slight characters. There is every gradation between the curved outer margin of the maxilliped of Myra fugax and the nearly straight margin in l'ersephona punctuta, and also between the elongated chelipeds of the former and the short, partly flattened chelipeds of the latter.

Randallia ornata Stimpson, Proc. Boston Soc. Nat. Hist., 1857, YI, 1, 85 ; Jour. Boston Soc. Nat. Hist., 1857, VI, p. 471 [31], pl. xx, fig. 3.
Magdalena Bay and off Abreojos Point, Lower California, $5 \frac{1}{2}$ to 51 fathoms, stations 2833, 2834, and 2835.

## 146. RANDALLIA AMERICANA Rathbun.

Ebalia americana Ratibun, Proc. U. S. Nat. Mus., 1893, XVI, p. 254.
Southern part of the Gulf of California, $9 \frac{1}{2}$ to $26 \frac{1}{2}$ fathoms, stations 2822,2823 , and between 2826 and 2828 .

## 147. RANDALLIA BULLIGERA, new species.

## (Plate XLIV, fig. 6.)

Large bead-like tubercles; five posterior protuberances; margin of efferent branchial channcl three-lobed and produced.

Carapace slightly longer than broad, covered except the frontal region with large, smooth, rounded, bead-like tubercles of different sizes and distinctly separated from one another; intervening space pubescent. Intestinal region bounded by a deep suture and having on the nedian line and a little behind the middle a larger tubercle composed of two or three smaller ones. Hepatic region bounded posteriorly by a deep suture; shallower and less marked sutures divide the branchial from the cardiac and gastric regions. Posterior margin with two lobate projections; a similar projection on the posterior margin of each branchial region. Of these four lobes the middle two are farther from each other than they are from the lateral. Pterygostomian region with a prominent blunt tuberculated projection. Frontal region covered with depressed gramules. Front moderately prominent (as in ormata), distinctly two-lobed. Sternum and abdomen covered with large tubercles. Maxillipeds with a longitudinal row of tubercles through the middle of the endognath and exognath; anterior half pubescent. Anterolateral angles of the buccal cavity produced in front of the orbital margin and deeply three-lobed. Exognath not reaching beyond the base of the lobes.

Merns of chelipeds covered with large tubercles; intervening spaces graunlate; leugth about three-fourths the width of the carapace in the male, one-half the width in the female; distal half slightly smaller than proximal. Cappus and propodus grauulate. Hands shaped much as in ornata; fingers a little shorter than the outer margin of the palm. Ambulatory legs granulate; dactyli with pubescent margins.

Dimcnsions.-Male: Length on median line, 11.6 mm .; width, 11.5 mm . Ovigerous female : Length, 12.8 mm . ; width, 12.6 mm .

Types.-No. 21600, U.S.N.M. One male, two females. Magdalena Bay, Lower California, 12 fathoms, station 2831.
148. RANDALLIA AGARICIAS, new species.
(Plate XLIV, figs. 7, 7a.)

Mushroom-like tubercles; four posterior protuberances; margin of efferent branchial channel entire, not produced.

Carapace slightly longer than broad. Posterior two-thirds convex and covered with large tubercles which have slightly convex surfaces
and are momited on short thickened stalks like mushrooms (Plate XLIV, fig. $7 a$ ). On the anterior third there is a median ridge extending from the front across the gastric region; on either side is a hollow; surface covered with depressed granules. Hepatic region convex; pterygostomian region bluntly angular; neither is armed. Intestinal region distinctly outlined. Posterior margin with two broad rounded tuberculate lobes. Postero-lateral margin of the branchial region armed with a smaller tuberculate lobe. The front has a blunt tooth at either end. Abdomen and sternum covered with bead-like tubercles. The maxillipeds are covered with large and irregular tubercles. The anterior angles of the buccal cavity are about equally advanced with the orbital wall and are not incised as in ormata and bulligera.

Chelipeds covered with tubercles similar to those of the carapace; the largest ones are on the merns and the outer surface of the carpus and propodus. Length of merus about the width of the carapace. The dactylus is less than two-thirds the length of the outer margin of the propodus. The propodus is rather narrow, its width being less than half its exterior length. Ambulatory legs granulate, with marginal rows of mushroom-like granules.

Dimensions.-Male: Median length, 8.5 mm.; width, 8.3 mm . Male: Median length, 9.2 mm .; wilth, 9 mm . Female: Median length, 8.2 mm .; wilth, 8.1 mm .

Types.-No. 21601, U.S.N.M. Three males, two females. Off Cape St. Lucas, Lower California, 31 fathoms, station $28: 9$.
